## 1. General Description

Fortasa USB Disk Module (UDM) is a high performance, embedded solid state drive (SSD) designed to replace a conventional IDE hard disk drive. UDM SSD can be plugged into a standard Embedded USB connector commonly found in desktops, portable PC systems and industrial PC systems. This product is well suited for embedded flash storage applications offering new and expanded functionality small form factor, better performance and increased reliability.

### 1.1 Performance-optimized Controller

The heart of an UDM is the USB controller, which translates standard USB signals into the data and controls of the flash media. This proprietary USB controller is specifically designed to attain high data throughput from host to flash.

#### 1.1.1 Error Correction Code (ECC)

The UDM uses BCH Error Detection Code (EDC) and Error Correction Code (ECC) algorithms which corrects up to 24 random single-bit errors for each 1024 byte block of data. High performance is achieved through hardware-based error detection and correction.

#### 1.1.2 Wear-Leveling

Flash memory can be erased a limited number of times. This number is called the erase cycle limit, or write endurance limit. The erase cycle limit applies to each individual erase block in the flash device. In a typical application, and especially if a file system is used, specific pages are constantly updated (e.g. the page that contains the FAT, registry, etc.). Without any special handling, these pages would wear out more rapidly than other pages, reducing the lifetime of the entire flash.

To overcome this inherent deficiency, Fortasa's USB-Disk Module (UDM) uses wear-leveling algorithm. This wear-leveling method ensures that consecutive writes of a specific sector are not written physically to the same page in the flash. This algorithm spreads flash media usage evenly across all pages, thereby maximizing flash lifetime.

#### 1.1.3 Write Protection Mode (optional)

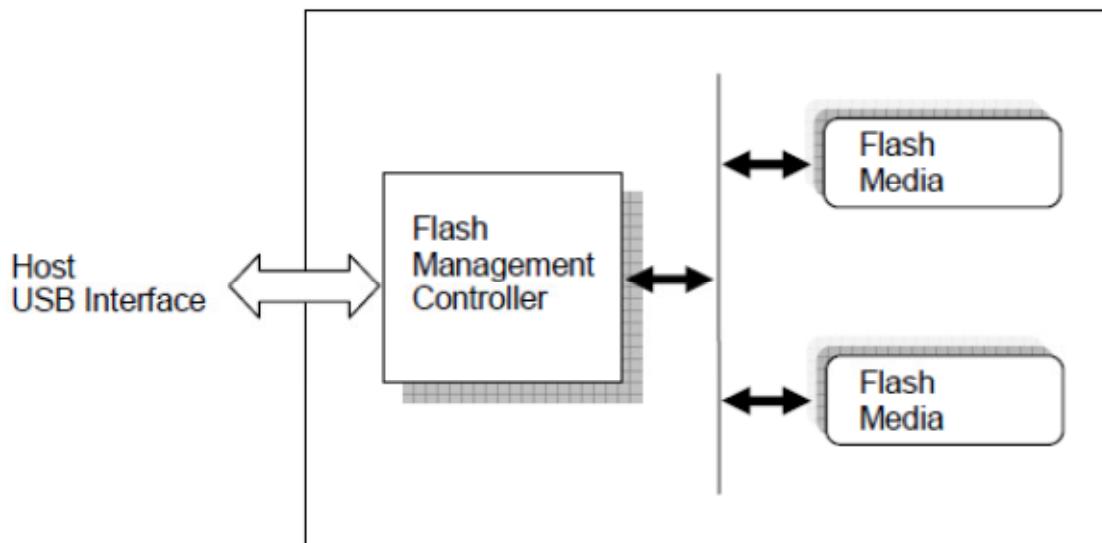

An optional write protection switch feature prevents the stored data from inadvertent system writes or erases, and viruses.

#### 1.1.4 S.M.A.R.T. Technology

S.M.A.R.T. is an acronym for Self-Monitoring, Analysis and Reporting Technology, an open standard allowing disk drives to automatically monitor their own health and report potential problems. It protects the user from unscheduled downtime by monitoring and storing critical drive performance and calibration parameters. Ideally, this should allow taking proactive actions to prevent impending drive failure.

## 2. Functional Block Diagram

The USB-Disk Module (UDM) contains a controller, embedded firmware, and Flash Media with a female connector. The UDM interfaces with the host system allowing data to be written to and read from the Flash Media.
